- China
- The Results for South Korea
 Conclusion

1. Introduction

O The share of tertiary industry in GDP in China is much lower than that of other countries with the similar economy

1. Introduction

- O The share of tertiary industry in China increased slowly since 2000
- O What is the main factors driving the structural changes? Will the proportion of tertiary industry increase or still keep steady in the future, for example, the next 5 years?
- O We answer this questions by an decomposition model based on constant price I/O tables.

O We analysis the change of tertiary industry share from the demand side

```
including : the Household Consumption, Investment,
```

the Intermediate Input, the Net Export and Price.

The basic balance between supply and demand in volume term can be written as:

$$X = AX + F^{C} + F^{IN} + E - IM$$

Where $X = [x_i]$ represents the column vector of total output for each sector (industries), $A = a_{ij} = [x_{ij} / x_j]$ is the matrix of input-output coefficients. AX indicates the intermediate input. $F^C = [f_i^c]$ is the column vector of consumption. $F^{IN} = [f_i^{in}]$ is total investment vector(including gross capital formation and change in inventories). $E = [e_i]$ is export vector, $IM = [im_i]$ import vector, so E - IM represents net export.

We can shift the above value-based equation to quantity-based equation:

$$X = AX + F^{C} + F^{IN} + E - IM$$

$$PX = APX + PF^{C} + PF^{IN} + PE - PIM$$

$$PX = (I - A)^{-1}(PF^{C} + PF^{IN} + PNE)$$

Since the proportion of the value added of tertiary industry in GDP is concerned, we get the value added vector according to the I/O table:

$$Y = VPX$$

 $Y = [y_i]_{\text{each sector}}^{\text{is the column vector of added value of}}$

 $V = [v_j/X_j]$ is value added coefficient for each secto

then the share of value added of each sector in GDP can be shown by the following equation:

$$\frac{1}{\sum_{i} y_{i}} Y = \frac{1}{\sum_{i} y_{i}} VPX = \frac{1}{\sum_{i} y_{i}} V(I - A)^{-1} (PF^{C} + PF^{IN} + PNE)$$

Denote
$$\theta = \frac{1}{\sum_{i} y_{i}} Y$$
 $M = V[I - A]^{-1} N = \frac{\left(F_{i}^{C} + F_{i}^{IN} + NE_{i}\right)}{\sum_{i} \left(P_{i}F_{i}^{C} + P_{i}F_{i}^{IN} + P_{i}NE_{i}\right)}$

Then
$$\theta = MPN$$

the share change of each sector can be decomposed by the following equation:

$$\theta_1 - \theta_0 = M_1 P_1 N_1 - M_0 P_0 N_0$$

Where the subscript 1 denotes the terminal year, while the subscript 0 denotes the base year.

Denote subscript c as value at constant price:

$$\begin{aligned} \theta_1 &- \theta_0 \\ &= \underbrace{\left(M_{c1} P_c \ N_{c1} - M_{c0} P_c \ N_{c0} \right)}_{\text{the effect due to other factors other than price}} \\ &+ \underbrace{\left[\left(M_1 \ P_1 \ N_1 \ - M_{c1} P_c \ N_{c1} \right) - \left(M_{c0} P_c \ N_{c0} - M_0 P_0 \ N_0 \right) \right]}_{\text{the effect due to price change}} \end{aligned}$$

2. The Data

The China constant prices I/O tables include the year of 1981、1983、1987、1990、1992 with constant price in 1990 and the tables of 1992, 1997, 2002, 2005 with constant price in 2000.

The constant price and current price I/O tables from 1975 to 2005 and 2007 of South Korea comes from the website of National Bureau of statistics of Korea.

3. The decomposition Result for China (%)

1. Price was the most important factor to contribute to increasing the share of tertiary industry in GDP

The important role of price should be contributed to the fact that the service price raise quickly comparing with price of goods in other industries. Example: the price index of tertiary industry increased by 16.8 % while the price index of secondary industry decreased by 6.5% from 1997 to 2002

2002

| | 1981- 1983 | 1983– 1987 | 1987- 1990 | 1990- 1992 | 1992– 1997 | 1997- 2002 | 2002- 2005 | total |
|--|---------------|---------------|---------------|---------------|---------------|---------------|---------------|-------|

| Price | -0.3 | 3. 1 | 5.8 | 6. 5 | -1.0 | 8. 1 | -0.1 | 22. 1 |

2. Household consumption structure was talk to tan structure factor

to increase the share of tertiary industry.

The household consumption structure upgrade steadily along with the economic growth, the Engel coefficient decreased from 56.7% (urban) and 61.8% (rural) in 1980 to 36.7% and 45.5% in 2005.

the proportion of services in total household consumption increased from 29.4% in 1992 to 46.0% in

| 2005 | 1981– 1983 | 1983- 1987 | 1987- 1990 | 1990- 1992 | 1992- 1997 | 1997- 2002 | 2002- 2005 | total |
|--|---------------|---------------|---------------|---------------|---------------|---------------|---------------|-------|

| Household Consumption structure | 2.3 | 0.2 | 0.6 | -1.5 | 0.2 | 3.6 | 0.8 | 6. 1 |

3. R Net export also raised the share of tertiary to council

industry in GDP

The effect of net export to the GDP structure is not steady in the whole periods. Depending on the change of net export structure.

- The proportion of services in total net export increased from 66% to 123.8% from 1997 to 2002. As a result, the share of tertiary industry increased
 - 0.99 percentage point.; The proportion of services in total net export decreased from 123.8% to 60.2% and the share of

| Consumption ratio in GDP | -0.02 | 0.05 | 0. 12 | 0.02 | 0.08 | 0.03 | -0.02 | 0. 3 |

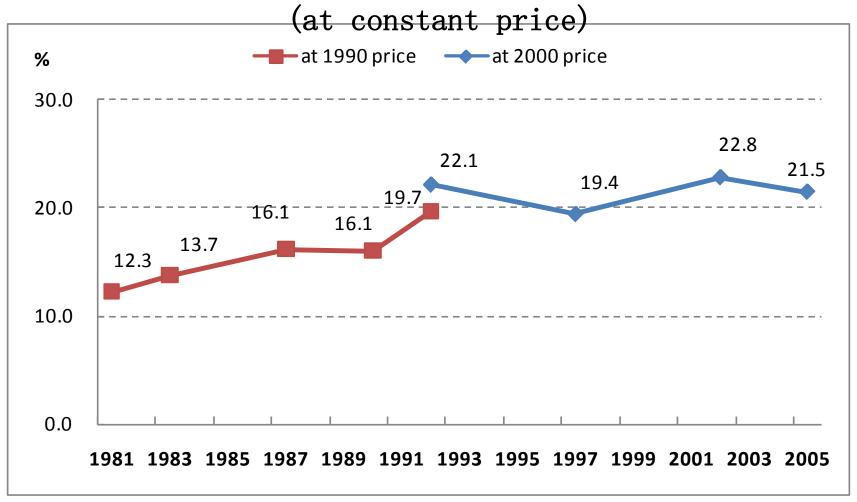

5. Intermediate input had the largest negative effects on the share of tertiary industry in GDP

The intermediate input made the share of tertiary industry GDP decline by 8.3 percentage points from 1981 to 2005. Chenery (1986) pointed out that one of important factors in driving the industrialization is the increasing using of intermediate input.

| | 1981– 1983 | 1983- 1987 | 1987- 1990 | 1990- 1992 | 1992- 1997 | 1997- 2002 | 2002- 2005 | total |

(at constant price)

development research center of the state council Government consumption was also a factor reducing

the share of tertiary industry in GDP

Since the reform and open door policy was implemented in 1978, the government reduced its expenditures on some fields.

For example, the tuition for undergraduate is paid mainly by household instead of the government recently.

Te share of government consumption in GDP decreased from 16.1% in 1981-o 1992 -1997 -2002 total 2005 1997 2002 The change of tertiary 0.47. 2 2.0 3. 2 -0.67.3 18.1 -1.4industry share in GDP • • • -0.6-3.3-0.6-0.6-1.01. 1 -1.1-0.5Government consumption

7. The change of Investment ratio to GDP reduced the share of

tertiary industry, but the effect was small

| | 1981– 1983 | 1983- 1987 | 1987- 1990 | 1990- 1992 | 1992– 1997 | 1997- 2002 | 2002- 2005 | total |

- 1. Price was the main factor raising the proportion of the tertiary industry in GDP
- 2. Consumption structure was also an important factor in increasing the share of tertiary industry in South Korean
- 3. The ratio of consumption in GDP had small effect on the

change of tertiary industry share.

- 4. Net export had the largest negative effect on the share of tertiary industry in GDP
- 5. Intermediate input, investment and government construction
- 2010/9/16 dropped the share of tertiary industry in of time.

The Results Comparison Between China and South Korea

| | | CHINA | KOREA | CHINA | KOREA | |
|--|--------------------------|---------------------|-------|-------|-------|--|
| | | 1981-2005 1975-2007 | | CHINA | NUKEA | |

| | rm | 0. 7 | -1.4 | | | |

in GDP and the government spending have similar effects Comparison Between China and on the share of tertiary industry in GDP both in China

and Korea.

1) Price and consumption structure were the most important

factors for increasing the share of tertiary industry.

2) The contribution of consumption share (include government

and household consumption) in GDP to the share of tertiary

industry was small both in China and Korea

- 2. The role of intermediate input, investment and The impetits Comparison Between China and Korea Were different between China and Korea.
- 1) Intermediate input had the largest negative effects on the

proportion of Chinese tertiary industry in GDP, however, its effect was small in South Korea.

2) Investment decreased the share of tertiary industry in

China but raised that in Korea

3) Net export also had opposite effects in China and Korea

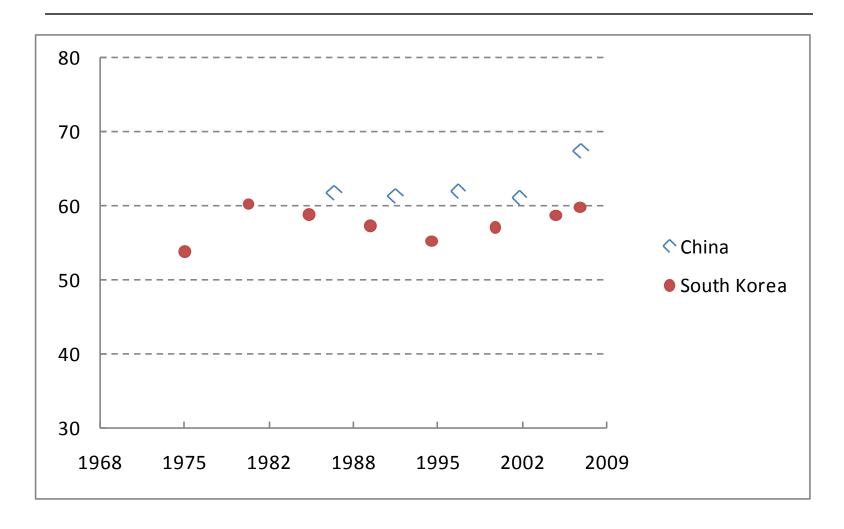

5. Conclusion and Forecasting

We suppose that the share of tertiary industry in GDP will be increased quickly in the twelfth five years plan period (2011-2015) and even longer time.

- Wage rise quickly in recent years and it will be raise continuously in the future, especially for some kind of labors.
 - The household consumption structure will be upgrade. The share of service expenditure in
- total consumption in China was only 46% in 2005, while that share in Korea has reached 69.3%.
 - The effect of intermediate input will become

^{2010/9/16} weak

Share of Total Intermediate Input to Total Output (at current price)
